

## Tide Prediction Error for the United States Stations

The accuracy of NOAA, National Ocean Service tide predictions is determined through a comparison of the predicted tides and observed water levels for all stations. Comparisons are made of the times and heights of high and low tides as well as hourly heights. Each water level station is unique; there is no single standard of accuracy when comparing the astronomical tide predictions and observed water levels.

Differences between predicted and observed tides will be greater than average during extreme weather events and during above normal river runoff to stations on tidal rivers. Errors in time and height of tide are generally larger for those areas with weaker tides.

The table below contains the tide stations that are used as reference stations in the NOAA tide table publication. Additional stations will be added in following years. The comparisons were made by subtracting the observations from the predictions, and computing a Root Mean Square (RMS) of the differences to estimate the average errors. These calculations were made using one year of data from each station.

As an example of how to interpret the RMS statistics, reference is made to Eastport, ME in the table below. At Eastport, ME the observed and predicted times of high water are within 0.11 hours of each other on average. Observed and predicted times of low water are within 0.12 hours on average. On average, the heights of observed and predicted high waters are within 0.147m (0.48 ft.); low waters are within 0.135m (0.44ft.); and hourly heights are within 0.143m (0.47ft.).

Station ID	Station Name	Analysis Year	High Water Time	Low Water Time	High Water Height	Low Water Height	Hourly Heights
